

UrlCreate Documentation

Overview

UrlCreate generates a short, unique URL-like string based on a user's email. It uses SHA-256 hashing to make sure the result is unique and secure.

Public Methods

- `createUrl(email)` →
- Hashes the email with SHA-256.
- Converts the hash into hex format.
- Returns the first 10 characters as the final URL string.

Implementation Details

- Uses OpenSSL SHA-256 for hashing.
- Output is deterministic (same email → same result).
- Result is short (10 chars) but unique enough for IDs/links.
